Mathematical Models for describing observable phenomena:

- Deterministic
- Probabilistic
Deterministic Models

• Ohm’s Law \( I = E/R \)

• Drop an object from height \( h_0 \). After \( t \) sec, height is \( h(t) = h_0 - 16t^2 \).

• Deposit $1000 in a continuously compounding checking 3% account. At time \( t \), it’s worth $1000e^{0.03t}$. 
Probabilistic Models — Involve uncertainty

• How much snow will fall tomorrow?

• Will IBM make a profit this year?

• Should I buy a call or put option?

• Can I win in blackjack if I use a certain strategy?
Some Cool Examples

1. Birthday Problem — Assume all 365 days have equal probability of being a person’s birthday (ignore Feb 29). Then...

If there are 23 people in the room, the odds are better than 50–50 that there will be a match.

If there are 50 people, the probability is about 97%!
2. Monopoly — In the long run, the property having the highest probability of being landed on is Illinois Ave.

3. Poker — Pick 5 cards from a standard deck. Then

\[
\begin{align*}
\Pr(\text{exactly 2 pairs}) & \approx 0.0475 \\
\Pr(\text{full house}) & \approx 0.00144 \\
\Pr(\text{flush}) & \approx 0.00198
\end{align*}
\]
4. Stock Market — Monkeys randomly selecting stocks could have outperformed most market analysts during the past year.

5. A couple has two kids and at least one is a boy. What’s the probability that BOTH are boys?

Possibilities: GG, BG, GB, BB. Eliminate GG since we know that there’s at least one boy. Then $\Pr(BB) = 1/3$. 
6. Vietnam Lottery

7. Ask Marilyn. You are a contestant at a game show. Behind one of three doors is a car; behind the other two are goats. You pick door A. Monty Hall opens door B and reveals a goat. Monty offers you a chance to switch to door C. What should you do?
Working Definitions

**Probability** — Methodology that describes the random variation in systems. (We’ll spend about 40% of our time on this.)

**Statistics** — Uses sample data to draw general conclusions about the population from which the sample was taken. (60% of our time.)
The Joy of Sets

Definition: A set is a collection of objects. Members of a set are called elements.

Notation:
$A, B, C, \ldots$ for sets; $a, b, c, \ldots$ for elements
$\in$ for membership, e.g., $x \in A$
$\notin$ for non-membership, e.g., $x \notin A$
$\emptyset$ is the universal set (i.e., everything)
$\emptyset$ is the empty set.
Examples:

$A = \{1, 2, \ldots, 10\}$. $2 \in A$, $49 \notin A$.

$B = \{\text{basketball, baseball}\}$

$C = \{x|0 \leq x \leq 1\}$ ("|" means "such that")

$D = \{x|x^2 = 9\} = \{\pm 3\}$ (either is fine)

$E = \{x|x \in \mathbb{R}, x^2 = -1\} = \emptyset$ ($\mathbb{R}$ is the real line)
Definition: If every element of set $A$ is an element of set $B$ then $A$ is a **subset** of $B$, i.e., $A \subseteq B$.

Definition: $A = B$ iff (if and only if) $A \subseteq B$ and $B \subseteq A$.

Properties:
- $\emptyset \subseteq A$; $A \subseteq U$; $A \subseteq A$
- $A \subseteq B$ and $B \subseteq C \Rightarrow$ (implies) $A \subseteq C$

Remark: Order of element listing is immaterial, e.g,\n\{a, b, c\} = \{b, c, a\}.
Definitions: **Complement** of $A$ with respect to $U$ is $\bar{A} \equiv \{x|x \in U \text{ and } x \notin A\}$.

**Intersection** of $A$ and $B$ is $A \cap B \equiv \{x|x \in A \text{ and } x \in B\}$.

**Union** of $A$ and $B$ is $A \cup B \equiv \{x|x \in A \text{ or } x \in B \text{ (or both)}\}$.

(Remember Venn diagrams?)
Example:

Suppose $U = \{\text{letters of the alphabet}\}$, $A = \{\text{vowels}\}$, and $B = \{a, b, c\}$. Then

$\overline{A} = \{\text{consonants}\}$

$A \cap B = \{a\}$

$A \cup B = \{a, b, c, e, i, o, u\}$

If $A \cap B = \emptyset$, then $A$ and $B$ are disjoint (or mutually exclusive).
Definitions:

Minus: \( A - B \equiv A \cap \bar{B} \)

Symmetric difference or XOR:

\[
A \Delta B \equiv (A - B) \cup (B - A) = (A \cup B) - (A \cap B)
\]

The cardinality of \( A \), \(|A|\), is the number of elements in \( A \). \( A \) is finite if \(|A| < \infty\).
Examples:

\[ A = \{3, 4\} \text{ is finite since } |A| = 2. \]

\[ B = \{1, 2, 3, \ldots\} \text{ is countably infinite.} \]

\[ C = \{x|x \in [0, 1]\} \text{ is uncountably infinite.} \]
1.2 Set Theory

Laws of Operation:

1. Complement Law: \( A \cup \bar{A} = U, \ A \cap \bar{A} = \emptyset, \ \bar{A} = A \)

2. Commutative: \( A \cup B = B \cup A, \ A \cap B = B \cap A \)

3. DeMorgan’s: \( \overline{A \cup B} = \bar{A} \cap \bar{B}, \ \overline{A \cap B} = \bar{A} \cup \bar{B} \)

4. Associative: \( A \cup (B \cup C) = (A \cup B) \cup C, \ A \cap (B \cap C) = (A \cap B) \cap C \)
5. Distributive: \( A \cup (B \cap C) = (A \cup B) \cap (A \cup C) \),
\( A \cap (B \cup C) = (A \cap B) \cup (A \cap C) \)

Proofs: Easy. Could use Venn diagrams or many other ways.
Experiments and Sample Spaces

Consider a “random” experiment:

\( E_1 \): Toss a die and observe the outcome.

Definition: A **sample space** associated with an experiment \( E \) is the set of *all* possible outcomes of \( E \). It’s usually denoted by \( S \) or \( \Omega \).
Examples:

$E_1$ has sample space $S_1 = \{1, 2, 3, 4, 5, 6\}$.

Another sample space for $E_1$ is $S'_1 = \{\text{odd, even}\}$.

So a sample space doesn’t have to be unique!
1.3 Experiments

$E_2$: Toss a coin 3 times and observe the sequence of $H$'s and $T$'s.

$S_2 = \{HHH, HHT, HTH, HTT, THH, THT, TTH, TTT\}$.

$E_3$: A new light bulb is tested to see how long it lasts.

$S_3 = \{t|t \geq 0\}$. 
Definition: An **event** is a set of possible outcomes. Thus, any subset of $S$ is an event.

Example (for $E_1$): If $A_1$ is the event “an even number occurs,” then $A_1 = \{2, 4, 6\}$, i.e., when the die is tossed, we get 2 or 4 or 6.

Remark: $\emptyset$ is an event of $S$ ("nothing happens")
$S$ is an event of $S$ ("something happens")
Remark: If $A$ is an event, then $\overline{A}$ is the complementary (opposite) event.

Example (for $E_1$):

$A_1 = \{2, 4, 6\} \Rightarrow \overline{A}_1 = \{1, 3, 5\}$ (i.e., “an odd number occurs”)

Remark: If $A$ and $B$ are events, then $A \cup B$ and $A \cap B$ are events.
Example (for $E_2$): Let

$A_2 = \text{“exactly one } T \text{ was observed”}$

$= \{HHT, HTH, THH\}$

$B_2 = \text{“no } T \text{'s observed”} = \{HHH\}$

$C_2 = \text{“first coin is } H\”$

$= \{HHH, HHT, HTH, HTT\}$

Then

$A_2 \cup B_2 = \text{“at most one } T \text{ observed”}$

$= \{HHT, HTH, THH, HHH\}$

$A_2 \cap C_2 = \{HHT, HTH\}$
Probability Basics

Suppose $A$ is some event for a sample space $S$. What’s the prob that $A$ will occur, i.e., $\Pr(A)$?

Example: Toss a fair coin. $S = \{H, T\}$. What’s the prob that $H$ will come up?

$$\Pr(\{H\}) = \Pr(H) = \frac{1}{2}.$$ 

What does this mean?
Frequentist view: If the experiment were repeated $n$ times, where $n$ is very large, we’d expect about 1/2 of the tosses to be $H$’s.

$$\frac{\text{Total \# of } H \text{'s out of } n \text{ tosses}}{n} \approx \frac{1}{2}.$$ 

Example: Toss a fair die. $S = \{1, 2, 3, 4, 5, 6\}$, where each individual outcome has prob 1/6. Then $\Pr(1, 2) = 1/3$. 
1.4 Probability

Definition: With each event $A \subseteq S$, we associate a number $\Pr(A)$, called “the probability of $A$,” satisfying the following axioms:

(1) $0 \leq \Pr(A) \leq 1$ (prob’s are always betw. 0 and 1).

(2) $\Pr(S) = 1$ (prob of some outcome is 1). Example: Die. $\Pr(S) = \Pr(1, 2, 3, 4, 5, 6) = 1$. 
(3) If \( A \cap B = \emptyset \), then \( \Pr(A \cup B) = \Pr(A) + \Pr(B) \).
Example: \( \Pr(1 \text{ or } 2) = \Pr(1) + \Pr(2) = 1/6 + 1/6 = 1/3 \).

(4) Suppose \( A_1, A_2, \ldots \) is a sequence of disjoint events (i.e., \( A_i \cap A_j = \emptyset \) for \( i \neq j \)). Then

\[
\Pr\left( \bigcup_{i=1}^{\infty} A_i \right) = \sum_{i=1}^{\infty} \Pr(A_i).
\]
Example: Toss a coin until the first $H$ appears.

$$S = \{H, TH, TTH, TTTTH, \ldots\}.$$ 

Define the disjoint events

$$A_1 = \{H\}, A_2 = \{TH\}, A_3 = \{TTH\}, \ldots.$$ 

Then

$$1 = \Pr(S) = \Pr\left(\bigcup_{i=1}^{\infty} A_i\right) = \sum_{i=1}^{\infty} \Pr(A_i).$$
More Nifty Properties

Theorem 1: $\Pr(\emptyset) = 0$.

Proof: Since $A \cap \emptyset = \emptyset$, we have that $A$ and $\emptyset$ are disjoint. So Axiom (3) implies

$$\Pr(A) = \Pr(A \cup \emptyset) = \Pr(A) + \Pr(\emptyset).$$

Note: Converse is false: $\Pr(A) = 0$ does not imply $A = \emptyset$. Example: Pick a random number betw. 0 and 1.
Theorem 2: \( \Pr(\overline{A}) = 1 - \Pr(A) \). 

Proof:

\[
1 = \Pr(S) \quad \text{(by Axiom (2))}
\]
\[
= \Pr(A \cup \overline{A})
\]
\[
= \Pr(A) + \Pr(\overline{A}) \quad (A \cap \overline{A} = \emptyset; \ \text{Axiom (3)}).
\]

Example: The probability that it’ll rain tomorrow is one minus the probability that it won’t rain.
Theorem 3: For any two events $A$ and $B$, 

$$
\Pr(A \cup B) = \Pr(A) + \Pr(B) - \Pr(A \cap B)
$$

Proof: First observe that $B = (A \cap B) \cup (\bar{A} \cap B)$ where $A \cap B$ and $\bar{A} \cap B$ are disjoint. Thus

$$
\Pr(B) = \Pr(A \cap B) + \Pr(\bar{A} \cap B) \quad (\ast)
$$

and so

$$
\Pr(A \cup B) = \Pr(A) + \Pr(\bar{A} \cap B) \quad \text{(by \, (\ast))}
$$

(A, \bar{A} \cap B \text{ are disjoint})

$$
= \Pr(A) + \Pr(B) - \Pr(A \cap B) \quad \text{(by \, (\ast))}.
$$
Remark: Can also do an easy Venn diagram proof. (Subtract \( \Pr(A \cap B) \) to avoid double-counting.)

Remark: Axiom (3) is a “special case” of this theorem in which \( A \cap B = \emptyset \).
Example: Suppose there’s... 
40% chance of colder weather
10% chance of rain and colder weather
80% chance of rain or colder weather.

Find the chance of rain.

\[
\Pr(R) = \Pr(R \cup C) - \Pr(C) + \Pr(R \cap C)
\]

\[
= 0.8 - 0.4 + 0.1 = 0.5.
\]
Theorem 4: For any three events $A$, $B$, and $C$,

$$
\Pr(A \cup B \cup C) = \Pr(A) + \Pr(B) + \Pr(C) - \Pr(A \cap B) - \Pr(A \cap C) - \Pr(B \cap C) + \Pr(A \cap B \cap C)
$$

Remark: See any good prob book for a generalization to $\Pr(A_1 \cup A_2 \cup \cdots \cup A_n)$. It's called the principle of inclusion-exclusion.
Example: 75% of Atlantans jog ($J$), 20% like ice cream ($I$), and 40% enjoy music ($M$). Also, 15% $J$ and $I$, 30% $J$ and $M$, 10% $I$ and $M$, and 5% do all three. Find the prob that a random resident will engage in at least one of the three activities.

\[
P(J \cup I \cup M) \\
= P(J) + P(I) + P(M) \\
- P(J \cap I) - P(J \cap M) - P(I \cap M) \\
+ P(J \cap I \cap M) \\
= .75 + .20 + .40 - .15 - .30 - .10 + .05 = .85.\]
Find the prob of precisely one activity.

\[ P(J \cap \overline{I} \cap \overline{M}) + P(\overline{J} \cap I \cap \overline{M}) + P(\overline{J} \cap \overline{I} \cap M) \]
\[ = .35 + 0 + .05 = .40. \]

How’d we get those?? Use Venn diagram, starting from the center and building out.
(Bonus) Theorem 5: $A \subseteq B \Rightarrow \Pr(A) \leq \Pr(B)$.

Proof:

\[
\Pr(B) = \Pr(A \cup (\bar{A} \cap B)) \\
= \Pr(A) + \Pr(\bar{A} \cap B) \\
\geq \Pr(A).
\]

Remark: $A \subseteq B$ means that $B$ occurs whenever $A$ occurs; so the Theorem makes intuitive sense.
Finite Sample Spaces

Suppose $S$ is finite, say $S = \{a_1, a_2, \ldots, a_n\}$.

Let $B$ be an event consisting of $r$ ($\leq n$) outcomes, i.e., $B = \{a_{j_1}, a_{j_2}, \ldots, a_{j_r}\}$, where the $j_i$’s represent $r$ indices from $\{1, 2, \ldots, n\}$. Then $\Pr(B) = \sum_{i=1}^{r} \Pr(a_{j_i})$.

Note: “Choosing an object at random” means that each object has the same prob of being chosen.
Example: You have 2 red cards, a blue card, and a yellow. Pick one card at random.

\[ S = \{\text{red, blue, yellow}\} = \{a_1, a_2, a_3\} \]

\[ \Pr(a_1) = \frac{1}{2}, \, \Pr(a_2) = \frac{1}{4}, \, \Pr(a_3) = \frac{1}{4}. \]

\[ \Pr(\text{red or yellow}) = \Pr(a_1) + \Pr(a_3) = \frac{3}{4}. \]
Definition: A **simple sample space** (SSS) is a finite sample space in which all outcomes are *equally likely*.

Remark: In the above example, $S$ is *not* simple since $\Pr(a_1) \neq \Pr(a_2)$.

Example: Toss 2 fair coins.

$S = \{HH, HT, TH, TT\}$ is a SSS (all prob’s are $1/4$).

$S' = \{0, 1, 2\}$ (number of $H$'s) is *not* a SSS. Why?
Theorem: For any event \( A \) in a SSS \( S \),

\[
\Pr(A) = \frac{|A|}{|S|} = \frac{\text{\# elements in } A}{\text{\# elements in } S}.
\]

Example: Die. \( A = \{1, 2, 4, 6\} \) (each with prob 1/6).
\( \Pr(A) = 4/6. \)
Example: Roll a pair of dice. Possible results (each w.p. 1/36):

Counting Techniques — count the elements in events from a SSS.

Multiplication Rule

Addition Rule

Permutations

Combinations
Multiplication Rule

Two operations are performed one after the other:

(a) The first operation can be done in \( n_1 \) ways.
(b) Regardless of the way in which the first operation was performed, the second can be performed in \( n_2 \) ways.

The \# ways to perform the two operations together is \( n_1n_2 \).
Example: 3 ways to go from City A to B, and 4 ways to go from B to C. Then the you can go from A to C (via B) in 12 ways.

Example: Roll 2 dice. How many outcomes? (Assume $(3,2) \neq (2,3)$.) Answer is 36.
Example: Select 2 cards from a deck without replacement and care about order (i.e., \((Q\spadesuit, 7\clubsuit) \neq (7\clubsuit, Q\spadesuit)\)). How many ways can you do this? Answer: \(52 \cdot 51 = 2652\).

Example: Box of 10 sox — 2 red and 8 black. Pick 2 w/o repl.

(a) Let \(A\) be the event that both are red.

\[
\Pr(A) = \frac{\text{# ways to pick 2 reds}}{\text{# ways to pick 2 sox}} = \frac{2 \cdot 1}{10 \cdot 9} = \frac{1}{45}.
\]
(b) Let $B$ be the event that both are black.

$$
\Pr(B) = \frac{8 \cdot 7}{10 \cdot 9} = \frac{28}{45}.
$$

(c) Let $C$ be one of each color.

$$
\Pr(C) = 1 - \Pr(\overline{C})
= 1 - \Pr(A \cup B)
= 1 - \Pr(A) - \Pr(B) \quad (A \text{ and } B \text{ disjoint})
= 16/45.
$$
Remark: The multiplication rule can be extended to more than 2 operations.

Example: Flip 3 coins. \(2 \times 2 \times 2 = 8\) possible outcomes.

Example: Toss \(n\) dice. \(6^n\) possible outcomes.
Addition Rule

Can use method A in \( n_A \) ways.
Can use method B in \( n_B \) ways.
If only one method can be used, you have \( n_A + n_B \) ways of doing so.

Example: Go to Starbucks and have a muffin (blueberry or oatmeal) or a bagel (sesame, plain, salt), but not both. \( 2 + 3 = 5 \) choices.
Permutations

Definition: An arrangement of \( n \) symbols in a definite order is a permutation of the \( n \) symbols.

Example: How many ways to arrange the numbers 1,2,3? Answer: 6 ways — 123, 132, 213, 231, 312, 321.
Example: How many ways to arrange 1, 2, ..., \( n \)?

\[
\text{(choose first)} \times \text{(choose second)} \times \cdots \times \text{(choose } n\text{th)}
\]

\[
n(n - 1)(n - 2) \cdots 2 \times 1 = n!.
\]

Example: Baseball manager has 9 players on his team. Find the # of possible batting orders. Answer: 9! = 362880.
Definition: The \# of \( r \)-tuples we can make from \( n \) different symbols (each used at most once) is called the \# of \textbf{permutations of} \( n \) things taken \( r \)-at-a-time,

\[
P_{n,r} \equiv \frac{n!}{(n-r)!} \quad (*)
\]

Note that \( 0! = 1 \) and \( P_{n,n} = n! \).

Example: How many ways can you take two symbols from \( a, b, c, d \)? Ans: \( P_{4,2} = 4!/2! = 12 \) — \( ab, ac, ad, ba, bc, bd, ca, cb, cd, da, db, dc \).
Proof (of (\(\ast\)))::

\[ P_{n,r} = (\text{choose first})(\text{second})\cdots(\text{rth}) \]
\[ = n(n-1)(n-2)\cdots(n-r+1) \]
\[ = \frac{n(n-1)\cdots(n-r+1)(n-r)\cdots2\cdot1}{(n-r)\cdots2\cdot1} \]
\[ = \frac{n!}{(n-r)!}. \]
Example: How many ways to fill the first 4 positions of a batting order?

\[ n = 9 \text{ players, } r = 4 \text{ positions.} \]

\[ P_{9,4} = \frac{9!}{(9 - 4)!} = 3024 \text{ ways.} \]
Example: How many of these 3024 ways has Smith batting first?

Method 1: First 4 positions: (Smith,?,?,?). This is equiv to choosing 3 players from the remaining 8.

\[ P_{8,3} = \frac{8!}{(8-3)!} = 336 \text{ ways.} \]

Method 2: It’s clear that each of the 9 players is equally likely to bat first. Thus, \( \frac{3024}{9} = 336 \).
Example: How many license plates of 6 digits can be made from the numbers 1,2,\ldots,9\ldots

(a) with no repetitions? (e.g., 123465) \( P_{9,6} = \frac{9!}{3!} = 60480. \)

(b) allowing repetitions? (e.g., 123345 or 123465) 
\[ 9 \times 9 \times \cdots \times 9 = 9^6 = 531441. \]

(c) containing repetitions? 531441 – 60480 = 470961.
1.6 Counting Techniques

Combinations

Suppose we only want to count the number of ways to choose $r$ out of $n$ objects without regard to order, i.e., count the number of different subsets of these $n$ objects that contain exactly $r$ objects.

Example: How many subsets of \{1, 2, 3\} contain exactly 2 elements? (Order isn't important.)

3 subsets — \{1, 2\}, \{1, 3\}, \{2, 3\}
Definition: The number of subsets with $r$ elements of a set with $n$ elements is called the number of combinations of $n$ things taken $r$-at-a-time.

Notation: $\binom{n}{r}$ or $C_{n,r}$ (read as “$n$ choose $r$”). These are also called binomial coefficients.
Difference between permutations and combinations:

Combinations — not concerned w/order: \((a, b, c) = (b, a, c)\).

Permutations — concerned w/order: \((a, b, c) \neq (b, a, c)\).

The number of permutations of \(n\) things taken \(r\)-at-a-time is always as least as large as the number of combinations. In fact,...
Remark: Choosing a permutation is the same as first choosing a combination \textit{and} then putting the elements in order, i.e.,

\[
\frac{n!}{(n-r)!} = \binom{n}{r} r!
\]

So

\[
\binom{n}{r} = \frac{n!}{(n-r)!r!}.
\]

\[
\binom{n}{r} = \binom{n}{n-r}, \quad \binom{n}{0} = \binom{n}{n} = 1, \quad \binom{n}{1} = \binom{n}{n-1} = n.
\]
1.6 Counting Techniques

Binomial Theorem:

$$(x + y)^n = \sum_{i=0}^{n} \binom{n}{i} x^i y^{n-i}$$

This is where Pascal’s $\triangle$ comes from!

Corollary: Surprising fact:

$$\sum_{i=0}^{n} \binom{n}{i} = 2^n.$$ 

Proof:

$$2^n = (1 + 1)^n = \sum_{i=0}^{n} \binom{n}{i} 1^i 1^{n-i}.$$
Example: An NBA team has 12 players. How many ways can the coach choose the starting 5?

\[
\binom{12}{5} = \frac{12!}{5!7!} = 792.
\]

Example: Smith is one of the players on the team. How many of the 792 starting line-ups include him?

\[
\binom{11}{4} = \frac{11!}{4!7!} = 330.
\]

(Smith gets one of the five positions for free; there are now 4 left to be filled by the remaining 11 players.)
Example: 7 red shoes, 5 blues. Find the number of arrangements.

\[ \binom{12}{7} \]

I.e., how many ways to put 7 reds in 12 slots?

Answer: \( \binom{12}{7} \).
Some applications of counting techniques.

Hypergeometric problems

Permutations vs. Combinations

Birthday problem

Poker probabilities

Multinomial coefficients
Hypergeometric Distribution

You have $a$ objects of type 1 and $b$ objects of type 2.

Select $n$ objects w/o replacement from the $a + b$.

$$\Pr(k \text{ type 1’s were picked}) = \frac{\text{(\# ways to choose } k \text{ 1’s})(\text{choose } n - k \text{ 2’s})}{\text{\# ways to choose } n \text{ out of } a + b}$$

$$= \frac{{a \choose k} {b \choose n - k}}{{a + b \choose n}} \quad (\text{the hypergeometric distr’rn}).$$
Example: 25 sox in a box. 15 red, 10 blue. Pick 7 w/o replacement.

\[
\Pr(\text{exactly 3 reds are picked}) = \frac{\binom{15}{3} \binom{10}{4}}{\binom{25}{7}}
\]
Permutations vs. Combinations — It’s all how you approach the problem!

Example: 4 red marbles, 2 whites. Put them in a row in random order. Find...

(a) \( \Pr(2 \text{ end marbles are W}) \)
(b) \( \Pr(2 \text{ end marbles aren’t both W}) \)
(c) \( \Pr(2 \text{ W’s aren’t side by side}) \)
Method 1 (using permutations): Let the sample space
\[ S = \{\text{every random ordering of the 6 marbles}\}. \]

(a) \( A \): 2 end marbles are W — WRRRRW.

\[ |A| = 2!4! = 48 \Rightarrow \Pr(A) = \frac{|A|}{|S|} = \frac{48}{720} = \frac{1}{15}. \]

(b) \( \Pr(\bar{A}) = 1 - \Pr(A) = \frac{14}{15}. \)
(c) \( B \): 2 W’s side by side — WWRRRR or RWRRRR or \ldots \) or RRRRWW

\[
|B| = (\text{# ways to select pair of slots for 2 W’s}) \times (\text{# ways to insert W’s into pair of slots}) \times (\text{# ways to insert R’s into remaining slots})
\]

\[
= 5 \times 2! \times 4! = 240.
\]

\[
\Pr(B) = \frac{|B|}{|S|} = \frac{240}{720} = \frac{1}{3}.
\]

But — The above method took too much time! Here’s an easier way\ldots
Method 2 (using combinations): Which 2 positions do the W’s occupy? Now let

\[ S = \{ \text{possible pairs of slots that the W’s occupy} \}. \]

Clearly, \(|S| = \binom{6}{2} = 15.\)

(a) Since the W’s must occupy the end slots in order for \(A\) to occur, \(|A| = 1 \Rightarrow \Pr(A) = |A|/|S| = 1/15.\)

(b) \(\Pr(\bar{A}) = 14/15.\)

(c) \(|B| = 5 \Rightarrow \Pr(B) = 5/15 = 1/3.\)
Birthday Problem

$n$ people in a room. Find the prob that at least two have the same birthday. (Ignore Feb. 29, and assume that all 365 days have equal prob.)

A: All birthdays are different.

$S = \{(x_1, \ldots, x_n) : x_i = 1, 2, \ldots, 365\}$ ($x_i$ is person $i$’s birthday), and note that $|S| = (365)^n$. 

[Page 72]
\[ |A| = P_{365,n} = (365)(364) \cdots (365 - n + 1) \]

\[
\Pr(A) = \frac{(365)(364) \cdots (365 - n + 1)}{(365)^n} = 1 \cdot \frac{364}{365} \cdot \frac{363}{365} \cdots \frac{365 - n + 1}{365}
\]

We want

\[
\Pr(\bar{A}) = 1 - \left( 1 \cdot \frac{364}{365} \cdot \frac{363}{365} \cdots \frac{365 - n + 1}{365} \right)
\]
Notes: When $n = 366$, $\Pr(\overline{A}) = 1$.

For $\Pr(\overline{A})$ to be $> 1/2$, $n$ must be $\geq 23$. (surprising)

When $n = 50$, $\Pr(\overline{A}) = 0.97$. 
Poker Problems

Draw 5 cards at random from a standard deck.

\[ |S| = \binom{52}{5} = 2,598,960. \]

Terminology:
rank = 2, 3, ..., Q, K, A,
suit = ♠, ♥, ♦, ♣
(a) 2 pairs — e.g., $A\heartsuit, A\spadesuit, 3\heartsuit, 3\diamondsuit, 10\spadesuit$

Select 2 ranks (e.g., $A, 3$). Can do this $\binom{13}{2}$ ways.

Select 2 suits for first pair (e.g., $\heartsuit, \spadesuit$). $\binom{4}{2}$ ways.

Select 2 suits for second pair (e.g., $\heartsuit, \diamondsuit$). $\binom{4}{2}$ ways.

Select remaining card to complete the hand. 44 ways.

$$|\text{2 pairs}| = \binom{13}{2} \binom{4}{2} \binom{4}{2} 44 = 123,552$$

$$\Pr(\text{2 pairs}) = \frac{123,552}{2,598,960} \approx 0.0475.$$
(b) Full house (1 pair, 3-of-a-kind) —
e.g., $A\heartsuit, A\spadesuit, 3\heartsuit, 3\diamondsuit, 3\spadesuit$

Select 2 ordered ranks (e.g., $A, 3$). $P_{13,2}$ ways.
Select 2 suits for pair (e.g., $\heartsuit, \spadesuit$). $\binom{4}{2}$ ways.
Select 3 suits for 3-of-a-kind (e.g., $\heartsuit, \diamondsuit, \spadesuit$). $\binom{4}{3}$ ways.

\[ |\text{full house}| = 13 \cdot 12 \left( \binom{4}{2} \right) \left( \binom{4}{3} \right) = 3744 \]

\[ \Pr(\text{full house}) = \frac{3744}{2,598,960} \approx 0.00144. \]
(c) Flush (all 5 cards from same suit)

Select a suit. \( \binom{4}{1} \) ways.

Select 5 cards from that suit. \( \binom{13}{5} \) ways.

\[
Pr(\text{flush}) = \frac{5148}{2,598,960} \approx 0.00198.
\]
(d) Straight (5 ranks in a row)

Select a starting point for the straight \((A, 2, 3, \ldots, 10)\). \(\binom{10}{1}\) ways.

Select a suit for each card in the straight. \(4^5\) ways.

\[
\text{Pr(straight)} = \frac{10 \cdot 4^5}{2,598,960} \approx 0.00394.
\]
1.7 Counting Applications

(e) Straight flush

Select a starting point for the straight. 10 ways.
Select a suit. 4 ways.

\[ \Pr(\text{straight flush}) = \frac{40}{2,598,960} \approx 0.0000154. \]
1.7 Counting Applications

Multinomial Coefficients

Example: \( n_1 \) blue sox, \( n_2 \) reds. \# of assortments is \( \binom{n_1 + n_2}{n_1} \) (binomial coefficients).

Generalization (for \( k \) types of objects): \( n = \sum_{i=1}^{k} n_i \)

\# of arrangements is \( n!/(n_1!n_2! \cdots n_k!) \).
Example: How many ways can “Mississippi” be arranged?

\[
\frac{\text{# perm’s of 11 letters}}{(\# \ m’\text{s})!(\# \ p’\text{s})!(\# \ i’\text{s})!(\# \ s’\text{s})!} = \frac{11!}{1!2!4!4!} = 34,650.
\]
Conditional Probability

Definition

Properties

Independence
Conditional Probability

Example: Die. \( A = \{2, 4, 6\} \), \( B = \{1, 2, 3, 4, 5\} \). So \( \Pr(A) = 1/2 \), \( \Pr(B) = 5/6 \).

Suppose we know that \( B \) occurs. Then the prob of \( A \) “given” \( B \) is

\[
\Pr(A|B) = \frac{2}{5} = \frac{|A \cap B|}{|B|}
\]

So the prob of \( A \) depends on the info that you have! The info that \( B \) occurs allows us to regard \( B \) as a new, restricted sample space. And...
1.8 Conditional Probability

\[
\Pr(A|B) = \frac{|A \cap B|}{|B|} = \frac{|A \cap B|/|S|}{|B|/|S|} = \frac{\Pr(A \cap B)}{\Pr(B)}.
\]

Definition: If \( \Pr(B) > 0 \), the **conditional prob of** \( A \) **given** \( B \) is \( \Pr(A|B) \equiv \Pr(A \cap B)/\Pr(B) \).

Remarks: If \( A \) and \( B \) are disjoint, then \( \Pr(A|B) = 0 \). (If \( B \) occurs, there’s no chance that \( A \) can also occur.)

What happens if \( \Pr(B) = 0 \)? Don’t worry! In this case, makes no sense to consider \( \Pr(A|B) \).
Example: Toss 2 dice and take the sum.

$A$: odd toss $= \{3, 5, 7, 9, 11\}$

$B$: $\{2, 3\}$

$\Pr(A) = \Pr(3) + \cdots + \Pr(11) = \frac{2}{36} + \frac{4}{36} + \cdots + \frac{2}{36} = \frac{1}{2}$.

$\Pr(B) = \frac{1}{36} + \frac{2}{36} = \frac{1}{12}$.

$\Pr(A|B) = \frac{\Pr(A \cap B)}{\Pr(B)} = \frac{\Pr(3)}{\Pr(B)} = \frac{2/36}{1/12} = \frac{2}{3}$. 
Example: 4 white sox, 8 red. Select 2 w/o repl.

A: 1st sock W; B: 2nd W; C: Both W (= A \cap B).

Pr(C) = Pr(A \cap B) = Pr(A)Pr(B|A) = \frac{4}{12} \cdot \frac{3}{11} = \frac{1}{11}.

Pr(B) = Pr(A \cap B) + Pr(\bar{A} \cap B)

= Pr(A)Pr(B|A) + Pr(\bar{A})Pr(B|\bar{A})

= \frac{4}{12} \cdot \frac{3}{11} + \frac{8}{12} \cdot \frac{4}{11} = \frac{1}{3}.

Could you have gotten this result w/o thinking?
A couple has two kids and at least one is a boy. What’s the prob that BOTH are boys?

\[ S = \{GG, GB, BG, BB\}, \text{ (‘BG’ means ‘boy then girl’) } \]

\[ C: \text{ Both are boys} = \{BB\}. \]

\[ D: \text{ At least 1 is a boy.} = \{GB, BG, BB\}. \]

\[ \Pr(C|D) = \frac{\Pr(C \cap D)}{\Pr(D)} = \frac{\Pr(C)}{\Pr(D)} = 1/3. \]

(My intuition was 1/2 — the \textit{wrong} answer! The problem was that we didn’t know whether \( D \) meant the first or second kid.)
Properties — analogous to Axioms of probability.

(1’) \( 0 \leq \Pr(A|B) \leq 1. \)

(2’) \( \Pr(S|B) = 1. \)

(3’) \( A_1 \cap A_2 = \emptyset \Rightarrow \Pr(A_1 \cup A_2|B) = \Pr(A_1|B) + \Pr(A_2|B). \)

(4’) If \( A_1, A_2, \ldots \) are all disjoint, then

\[
\Pr\left( \bigcup_{i=1}^{\infty} A_i \bigg| B \right) = \sum_{i=1}^{\infty} \Pr(A_i|B).
\]
Independence Day — Any unrelated events are independent.

A: It rains on Mars tomorrow.  
B: Coin lands on $H$.

Definition: $A$ and $B$ are independent iff $\Pr(A \cap B) = \Pr(A)\Pr(B)$.

Example: If $\Pr($rains on Mars$) = 0.2$ and $\Pr(H) = 0.5$, then $\Pr($rains and $H$) $= 0.1$. 
Note: If $\Pr(A) = 0$, then $A$ is indep of any other event.

Remark: Events don’t have to be physically unrelated to be indep.

Example: Die. $A = \{2, 4, 6\}$, $B = \{1, 2, 3, 4\}$, $A \cap B = \{2, 4\}$, so $\Pr(A) = 1/2$, $\Pr(B) = 2/3$, $\Pr(A \cap B) = 1/3$.

$\Pr(A)\Pr(B) = 1/3 = \Pr(A \cap B) \Rightarrow A, B$ indep.
More natural interpretation of independence...

Theorem: Suppose $\Pr(B) > 0$. Then $A$ and $B$ are indep iff $\Pr(A|B) = \Pr(A)$.

Proof: $A, B$ indep $\iff \Pr(A \cap B) = \Pr(A)\Pr(B) \iff \Pr(A \cap B)/\Pr(B) = \Pr(A)$.

Remark: So if $A$ and $B$ are indep, the prob of $A$ doesn’t depend on whether or not $B$ occurs.
(Bonus) Theorem: $A, B$ indep $\Rightarrow A, \bar{B}$ indep.

Proof: $\Pr(A) = \Pr(A \cap \bar{B}) + \Pr(A \cap B)$, so that

$$\Pr(A \cap \bar{B}) = \Pr(A) - \Pr(A \cap B)$$
$$= \Pr(A) - \Pr(A)\Pr(B) \quad (A, B \text{ indep})$$
$$= \Pr(A)[1 - \Pr(B)] = \Pr(A)\Pr(\bar{B}).$$
Don’t confuse independence with disjointness!

Theorem: If $\Pr(A) > 0$ and $\Pr(B) > 0$, then $A$ and $B$ can’t be indep and disjt at the same time.

Proof: $A, B$ disjt $(A \cap B = \emptyset) \Rightarrow \Pr(A \cap B) = 0 < \Pr(A)\Pr(B)$. Thus $A, B$ not indep. Similarly, indep implies not disjt.
1.8 Conditional Probability

Extension to more than two events.

Definition: $A, B, C$ are indep iff

(a) $\Pr(A \cap B \cap C) = \Pr(A) \Pr(B) \Pr(C)$

and

(b) All *pairs* must be indep:

\[
\begin{align*}
\Pr(A \cap B) &= \Pr(A) \Pr(B) \\
\Pr(A \cap C) &= \Pr(A) \Pr(C) \\
\Pr(B \cap C) &= \Pr(B) \Pr(C)
\end{align*}
\]
Note that condition (a) by itself isn’t enough.

Example: \( S = \{1, 2, \ldots, 8\} \) (each element w.p. 1/8).
\( A = \{1, 2, 3, 4\} \), \( B = \{1, 5, 6, 7\} \), \( C = \{1, 2, 3, 8\} \).

(a) \( A \cap B \cap C = \{1\} \). \( \Pr(A \cap B \cap C) = \Pr(A)\Pr(B)\Pr(C) = 1/8 \), so (a) is satisfied. However, (b) is *not*...

(b) \( A \cap B = \{1\} \). \( \Pr(A \cap B) = 1/8 \neq 1/4 = \Pr(A)\Pr(B) \).
Also note that (b) by itself isn’t enough.

Example: \( S = \{1, 2, 3, 4\} \) (each element w.p. \( 1/4 \)). \( A = \{1, 2\} \), \( B = \{1, 3\} \), \( C = \{1, 4\} \). \( A \cap B = A \cap C = B \cap C = A \cap B \cap C = \{1\} \).

(b) \( \Pr(A \cap B) = 1/4 = \Pr(A)\Pr(B) \). Same deal with \( A, C \) and \( B, C \). So (b) is OK. But (a) \( isn’t \)...

(a) \( \Pr(A \cap B \cap C) = 1/4 \neq 1/8 = \Pr(A)\Pr(B)\Pr(C) \).
1.8 Conditional Probability

General Definition: $A_1, \ldots, A_k$ are indep iff
\[ \Pr(A_1 \cap \cdots \cap A_k) = \Pr(A_1) \cdots \Pr(A_k) \] and all subsets of \( \{A_1, \ldots, A_k\} \) are indep.

Independent Trials: Perform $n$ trials of an experiment such that the outcome of one trial is indep of the outcomes of the other trials.
Example: Flip 3 coins indep’ly.

(a) \( \Pr(1\text{st coin is } H) = 1/2 \). Don’t worry about the other two coins since they’re indep of the 1st.

(b) \( \Pr(1\text{st coin } H, \ 3\text{rd } T) = \Pr(1\text{st coin } H)\Pr(3\text{rd } T) = 1/4 \).

Remark: For indep trials, you just multiply the individual probs.
1.8 Conditional Probability

Example: Flip a coin infinitely many times (each flip is indep of the others).

\[ p_n \equiv \Pr(1\text{st }H \text{ on } n\text{th trial}) \]
\[ = \Pr(TT \cdots T H) \]
\[ = \underbrace{\Pr(T)\Pr(T) \cdots \Pr(T)}_{n-1} \Pr(H) = 1/2^n. \]

\[ \Pr(H \text{ eventually}) = \sum_{n=1}^{\infty} p_n = 1. \]
1.9 Bayes’ Theorem

Bayes’ Theorem

Partitions

Bayes’ Theorem

Examples
Partition of a sample space — split the sample space into disjoint, yet all-encompassing subsets.

Definition: The events $A_1, A_2, \ldots, A_n$ form a partition of the sample space $S$ if

1. $A_1, A_2, \ldots, A_n$ are disjoint.
2. $\bigcup_{i=1}^{n} A_i = S$.
3. $\Pr(A_i) > 0$ for all $i$. 

Remark: When an experiment is performed, \textit{exactly one} of the $A_i$’s occurs.

Example: $A$ and $\bar{A}$ form a partition.

Example: “vowels” and “consonants” form a partition of the letters.

Example: Suppose $A_1, A_2, \ldots, A_n$ form a partition of $S$, and $B$ is some arbitrary event. Then

$$B = \bigcup_{i=1}^{n} (A_i \cap B).$$
So if $A_1, A_2, \ldots, A_n$ is a partition,

$$
Pr(B) = Pr\left( \bigcup_{i=1}^{n} (A_i \cap B) \right)
$$

$$
= \sum_{i=1}^{n} Pr(A_i \cap B) \quad (A_1, A_2, \ldots, A_n \text{ are disjoint})
$$

$$
= \sum_{i=1}^{n} Pr(A_i)Pr(B|A_i) \quad \text{(by defn of cond’l prob)}.
$$

This is the **Law of Total Probability**.

Example: $Pr(B) = Pr(A)Pr(B|A) + Pr(\bar{A})Pr(B|\bar{A})$,

which we saw in the last module.
Bayes' Theorem: If \( A_1, A_2, \ldots, A_n \) form a partition of \( S \) and \( B \) is any event, then

\[
\Pr(A_i|B) = \frac{\Pr(A_i \cap B)}{\Pr(B)} = \frac{\Pr(A_i)\Pr(B|A_i)}{\sum_{j=1}^{n} \Pr(A_j)\Pr(B|A_j)}.
\]

The \( \Pr(A_i) \)'s are \textbf{prior} probabilities ("before \( B \)").

The \( \Pr(A_i|B) \)'s are \textbf{posterior} probabilities ("after \( B \)").

The \( \Pr(A_i|B) \) add up to 1. That's why the funny-looking denominator.
Example: In a certain city with good police, 
Pr(Any defendant brought to trial is guilty) = 0.99.

In any trial, 
Pr(Jury acquits if defendant is innocent) = 0.95. 
Pr(Jury convicts if defendant is guilty) = 0.95.

Find Pr(Defendant is innocent|Jury acquits).
Events: $I = \text{“innocent”}$, $G = \text{“guilty”} = \bar{I}$, $A = \text{“acquittal”}$. Since the partition is $\{I, G\}$, Bayes’ \[\Rightarrow \]

$$
Pr(I|A) = \frac{Pr(I)Pr(A|I)}{Pr(I)Pr(A|I) + Pr(G)Pr(A|G)}
$$

$$
= \frac{(0.01)(0.95)}{(0.01)(0.95) + (0.99)(0.05)}
$$

$$
= 0.161.
$$

Notice how the posterior prob’s depend strongly on the prior prob’s.
Example: A store gets 1/2 of its items from Factory 1, 1/4 from Factory 2, and 1/4 from Factory 3.

2% of Factory 1’s items are defective.
2% of Factory 2’s items are defective.
4% of Factory 3’s items are defective.

An item from the store is found to be bad. Find the prob it comes from Factory 1. [Answer should be < 1/2 since bad items favor Factory 3.]
Events: $F_i = \text{"Factory } i\text{"}$, $D = \text{"defective item"}$. Partition is $\{F_1, F_2, F_3\}$.

\[
\Pr(F_1|D) = \frac{\Pr(F_1)\Pr(D|F_1)}{\sum_{j=1}^{3} \Pr(F_j)\Pr(D|F_j)}
\]

\[
= \frac{(0.5)(0.02)}{(0.5)(0.02) + (0.25)(0.02) + (0.25)(0.04)}
\]

\[
= 0.4.
\]

It turns out that $\Pr(F_2|D) = 0.2$ and $\Pr(F_3|D) = 0.4$.
